

Section A2 — Depth-Based Heuristic Weighting

Modify your existing Minimax or Alpha-Beta implementation so that the evaluation heuristic changes according to the remaining search depth.

Use:

When remaining depth > 1:

$$H = 2(S_m - S_o) + (B_m - B_o)$$

When remaining depth = 1:

$$H = 5(S_m - S_o) + 3(B_m - B_o)$$

Where:

- B_m = total stones in the current player's six bins
- B_o = total stones in the opponent's six bins

Requirements:

1. Modify your search/evaluation code to apply the appropriate heuristic according to the remaining depth.
2. Run the program for a given depth.
3. Print the search depth, selected move, and final evaluation value.
